1 Metrics: what we measure and why

Every metric derives from one idea: ground truth (tx/rx positions) predicts the physical observable, so the wrapped residual between measured and predicted phase difference exposes both noise and systematics. The forward direction is immune to front/back ambiguity and d/λ>0.5 aliasing.

$$\phi_{pred} = -2\pi\,(d/\lambda)\,\sin(\theta_{gt} - \theta_{mount}) \qquad \delta\phi = \mathrm{pi\_norm}(\phi_{meas} - \phi_{pred})$$

phi_meas is the cached per-snapshot mean_phase from segmentation v3.7. All residual statistics are circular (wrap at ±π). Fits are per dataset × receiver; rover fits are distance-weighted (bearing noise ∝ 1/range).

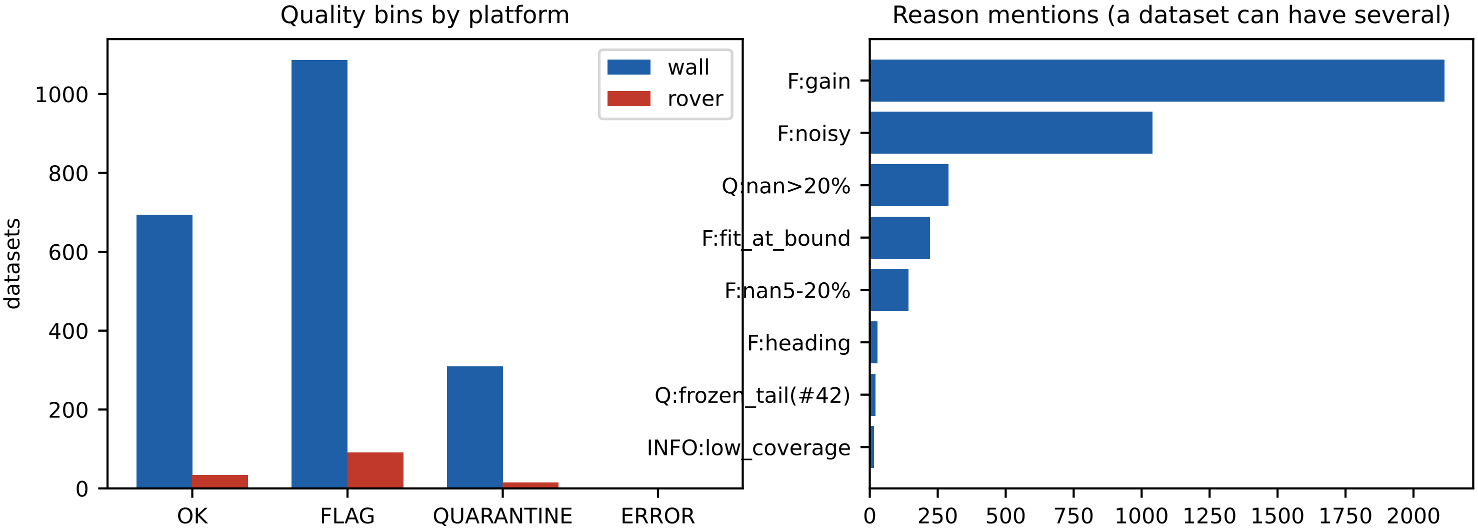
`TIER 1 — validity gates`	
`M1 nan_frac (r0/r1)`	fraction of snapshots with no valid mean_phase (no signal windows)
`M3 frozen_max_frac / frozen_tail`	longest run of identical tx+rx positions; tail = #42 signature
`M3b rx_speed_p99`	physical speed plausibility from positions + timestamps
`M4 ts_nonmono_frac / ts_med_dt`	timestamp order violations; median cadence
`TIER 2 — forward-model residual`	
`M5 bias`	circular mean of residual: phase offset / heading bias
`M6 circstd_raw / circstd_corr`	circular stddev before / after the fitted correction
`M7 outlier_frac`	fraction with |residual-bias| > 1 rad (multipath bursts, GT glitches)
`M8 g (gain)`	fitted scale on phi_pred: effective d/lambda = g × configured
`M9 dtheta`	fitted mount-angle shift; rover: common part = heading bias
`M11 drift_span`	spread of residual mean across 4 time-quarters (thermal drift)
`M12 structure`	dispersion of residual means across 12 theta bins (multipath/geometry)
`FIT MODEL (≤3 params/receiver)`	
`phi ~ c + g·(-2π d/λ)·sin(θ-Δθ)`	wall g∈[0.7,3.0], Δθ∈±0.35; rover g∈[0.9,1.1] (diagnostic), Δθ∈±0.9

GATES (v2 thresholds; platform-branched). WALL: QUARANTINE if nan>20% or frozen_tail; FLAG if nan 5-20%, |g-1|>0.25, corrected circstd>0.8, ts non-monotonic >1% of pairs, or fit at grid bound. ROVER: QUARANTINE if nan>90% or <100 valid snapshots; FLAG if |heading|>0.25, corrected circstd>0.7, ts>1%, or fit at bound. INFO:low_coverage marks fits skipped by the identifiability guard (does not change the bin).

SCANNER v2 (this scan): compared to v1, the wall g grid is widened to [0.7, 3.0] (the cfg-0.20λ group no longer pins at a bound), the rover Δθ grid to ±0.9 rad, the wall NaN gate is two-tier, the ts gate fires only above 1% of pairs, fits are skipped under narrow angular coverage (offset-only + INFO:low_coverage), errors are re-checked serially, and frozen-tail datasets carry a truncation index for salvage. Section 13 lists the remaining v3 roadmap.

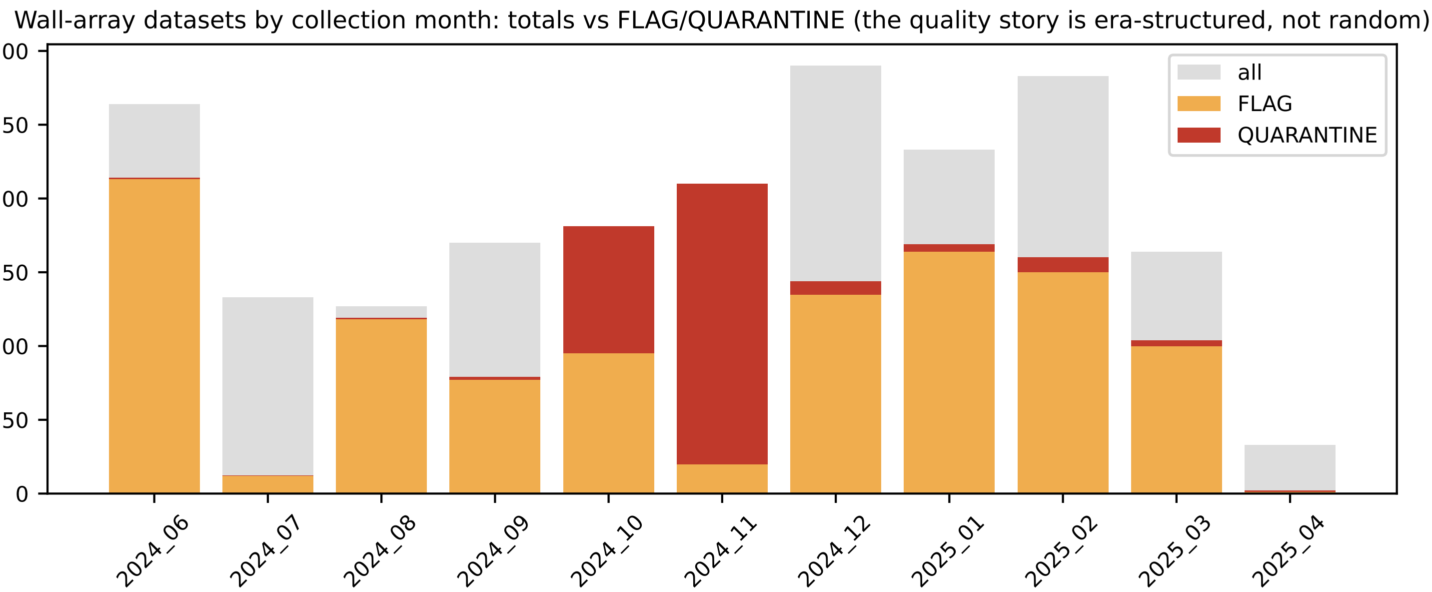
2 Fleet overview: quality bins

2,250 datasets: 2088 wall-array, 139 rover, 23 unclassifiable (scan errors). Quality bins are assigned by the platform-specific gates of section 1. The bins mean: OK = passes all gates; FLAG = usable but carries a measurable systematic or minor defect (most FLAGs are the correctable gain systematic, section 5); QUARANTINE = fails a validity gate (do not train on as-is); ERROR = could not be read (integrity failure, section 12).



DECOMPOSITION OF THE NON-OK BINS (v2 gates): the 1176 FLAG + 324 QUARANTINE + 23 ERROR are six distinct populations, most NOT bad data:

- 1268 wall FLAG:gain — real, tight, CORRECTABLE spacing systematic (keep + sidecar). [sec 5]
- 289 wall QUAR:nan>20% — month-clustered bad-capture era (Nov-24, Oct-24, Feb-25). [sec 7]
- 142 wall FLAG:nan5-20% — borderline duty-cycle tier (v2 two-tier gate). [sec 6]
- 564 noisy-valid-part mentions — largely the same bad months. [sec 7]
- 21 QUAR:frozen_tail — real #42 casualties; truncation index now recorded. [sec 9]
- 23 ERROR after serial retry — genuine integrity failures. [sec 12]



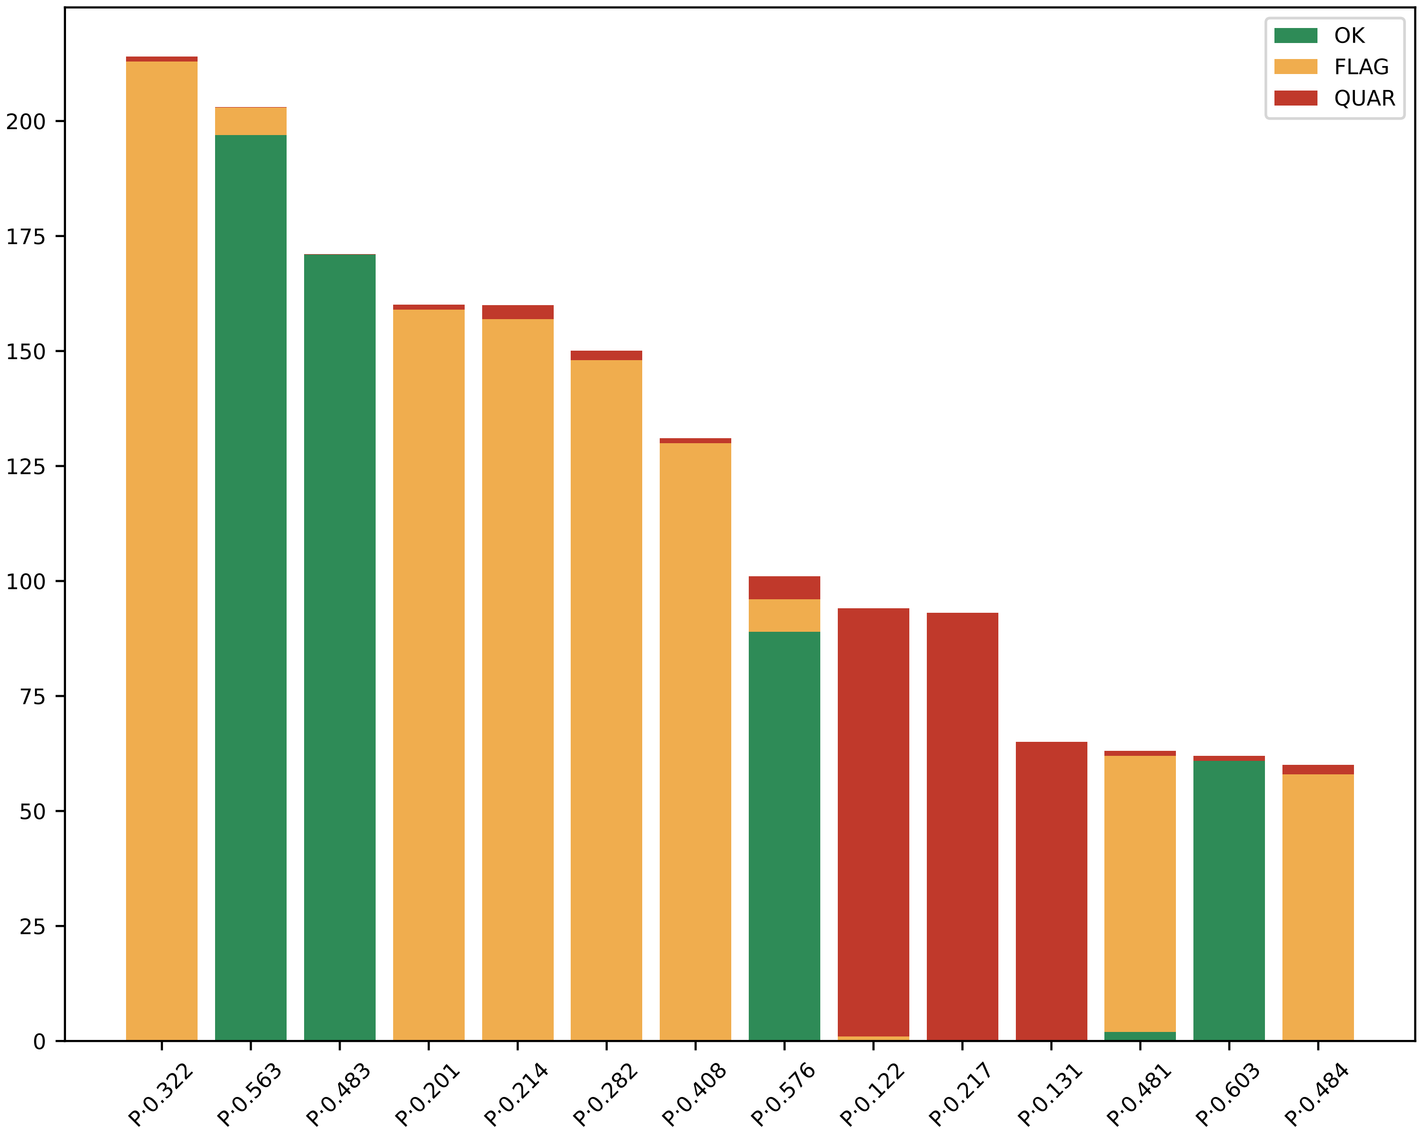
3 Wall-array breakdown (by device × spacing group)

2088 wall-array datasets ({'PLUTO': 2040, 'BLADERF2': 48}). Ground truth is GRBL steps (sub-mm), so residuals here measure the RF chain itself. The fleet is organized in (device × configured d/λ) groups — the natural calibration unit: gain, mount shift, and quality are tight within a group and differ across groups. Table W1 summarizes the largest groups; the stacked bars show where the quality bins live.

Table W1 — largest device × d/λ groups

device	cfg d/λ	n	med g	med corr	med NaN%	OK/FL/QU
PLUTO	0.322	214	1.62	0.59	0	0/213/ 1
PLUTO	0.563	203	1.02	0.50	0	197/ 6/ 0
PLUTO	0.483	171	1.14	0.61	0	171/ 0/ 0
PLUTO	0.201	160	2.14	0.64	0	0/159/ 1
PLUTO	0.214	160	1.11	0.95	2	0/157/ 3
PLUTO	0.282	150	1.78	0.56	0	0/148/ 2
PLUTO	0.408	131	1.38	0.60	0	0/130/ 1
PLUTO	0.576	101	0.90	0.36	0	89/ 7/ 5
PLUTO	0.122	94	0.86	0.93	26	0/ 1/ 93
PLUTO	0.217	93	1.44	1.13	33	0/ 0/ 93
PLUTO	0.131	65	1.08	0.98	26	0/ 0/ 65
PLUTO	0.481	63	1.16	0.46	2	2/ 60/ 1
PLUTO	0.603	62	0.98	0.54	0	61/ 0/ 1
PLUTO	0.484	60	1.18	0.40	1	0/ 58/ 2

Fig. W1 — quality bins per device × d/λ group (P=PLUTO, B=BLADERF2)



4 Rover breakdown (by era)

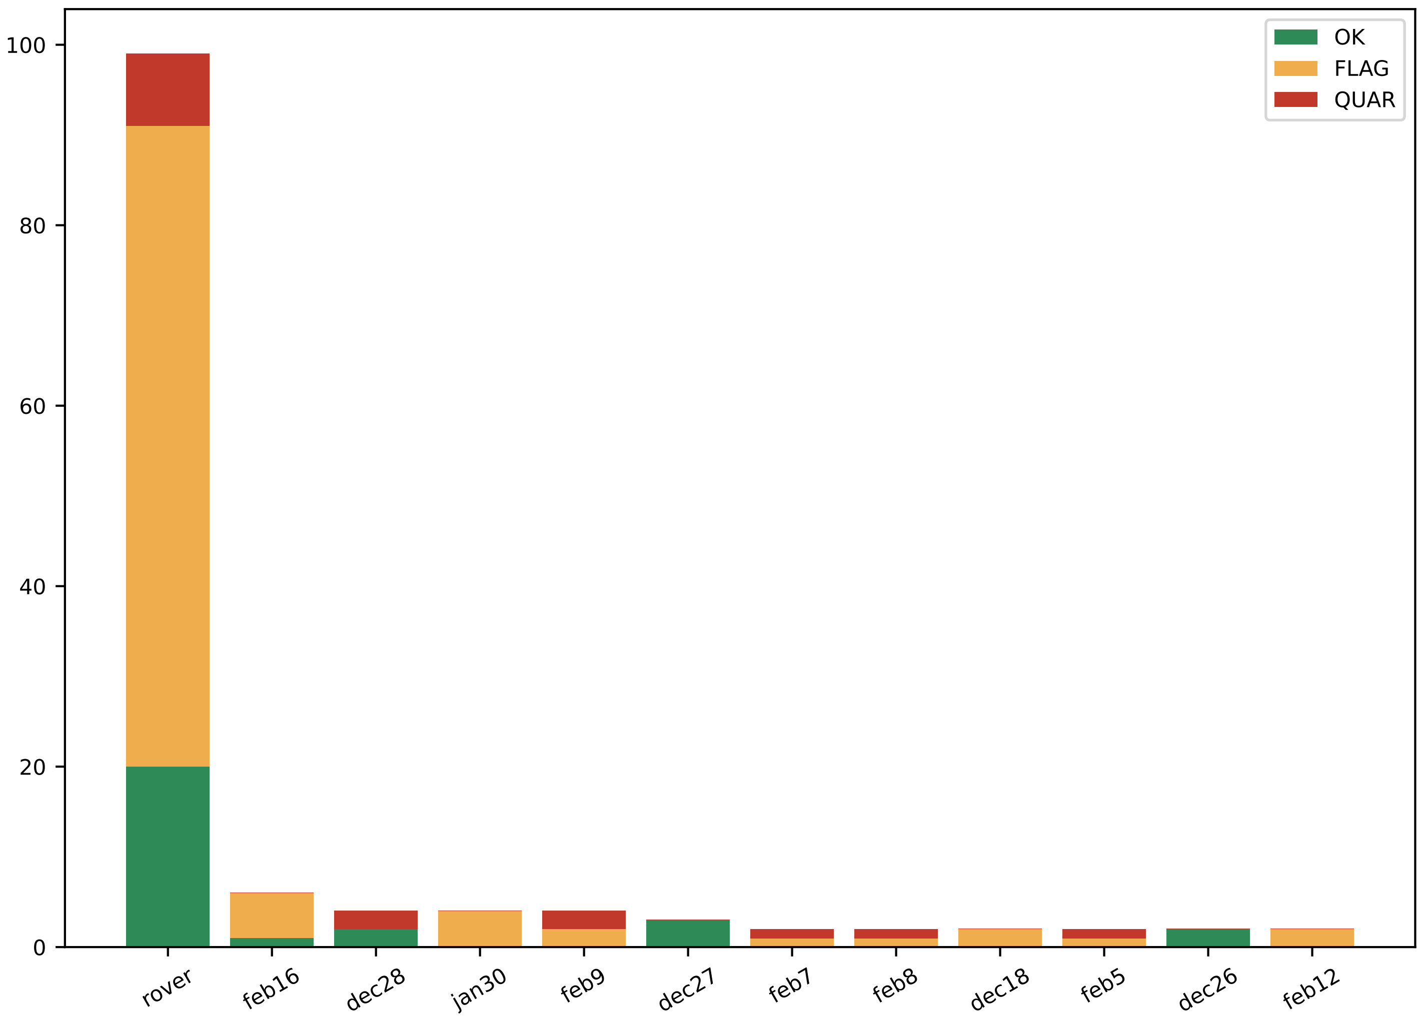
139 rover datasets. Ground truth is GPS + compass, so residuals are dominated by label noise (2-5 m GPS at 9-15 m range ⇒ 0.15-0.5 rad bearing noise floor); systematics appear as biases beneath it. The natural unit is the mission ERA (day/installation): heading bias and quality are stable within an era and jump between eras. Rover NaN baseline is 60-70% (bursty WiFi/o4 emitter)— high NaN alone is NOT a defect here (section 6).

Table R1 — mission eras

era	n	med NaN%	med corr	med heading	med range m	OK/FL/QU
rover	99	56	0.61	+0.05	37.3	20/ 71/ 8
feb16	6	40	0.77	-0.14	21.1	1/ 5/ 0
dec28	4	66	0.47	-0.12	13.2	2/ 0/ 2
jan30	4	69	0.91	-0.23	21.4	0/ 4/ 0
feb9	4	81	0.69	-0.21	21.4	0/ 2/ 2
dec27	3	68	0.50	-0.15	13.2	3/ 0/ 0
feb7	2	89	0.73	-0.12	21.0	0/ 1/ 1
feb8	2	82	0.75	-0.14	21.3	0/ 1/ 1
dec18	2	78	1.36	-0.03	0.0	0/ 2/ 0
feb5	2	83	0.69	-0.17	20.2	0/ 1/ 1
dec26	2	63	0.49	-0.15	13.4	2/ 0/ 0
feb12	2	51	0.76	-0.27	22.2	0/ 2/ 0

Reading: the 'rover' era (spring-2025 named runs) is the largest and near-zero heading bias; the Dec-Feb named-day eras carry the ≈−0.15 rad heading bias (section 8). Per-era OK/FLAG mixes are driven by circstd and ts flags; QUAR here means no_signal (fewer than 100 valid snapshots).

Fig. R1 — quality bins per rover era



5 Deep dive — wall effective-spacing (gain) systematic

THE FINDING. Fitting a gain g on the physics term shows the effective antenna spacing disagrees with the configured spacing for a structured subset of the wall fleet. This is not fit noise: the two independent receivers agree (corr 0.64, median |Δg| = 0.08, fig. A2) and per-config groups are razor-tight (e.g. cfg 0.32λ → IQR 1.56-1.66).

IN METERS (fig. A1): at 2.4 GHz every config below ~6 cm lands at an effective 6.2-7.3 cm (configs≥6 cm read correct) — a physical FLOOR, consistent with antenna body width. At 5.8 GHz configs≥4.3 cm are correct and the 2.5 cm config floors at ~3.3 cm. At 915 MHz the effect INVERTS: large configs (7-7.5 cm) read 1.3-1.6× larger — a floor cannot do that, pointing at mutual coupling (or actually-larger mounting) for that band.

CONSEQUENCE: rx_spacing_input to the NN and the spacing keys of the empirical tables are wrong for the sub-floor config groups. REMEDY: these datasets are healthy — apply the fitted effective d/λ as a 1-parameter sidecar; do NOT exclude. Root-cause (floor vs coupling) needs a physical rig check; both hypotheses predict floors that scale with λ (~0.5-0.6 λ), as observed.

Fig. A1 — effective vs configured antenna spacing
(marker size = # fits; bound-hitting fits excluded)

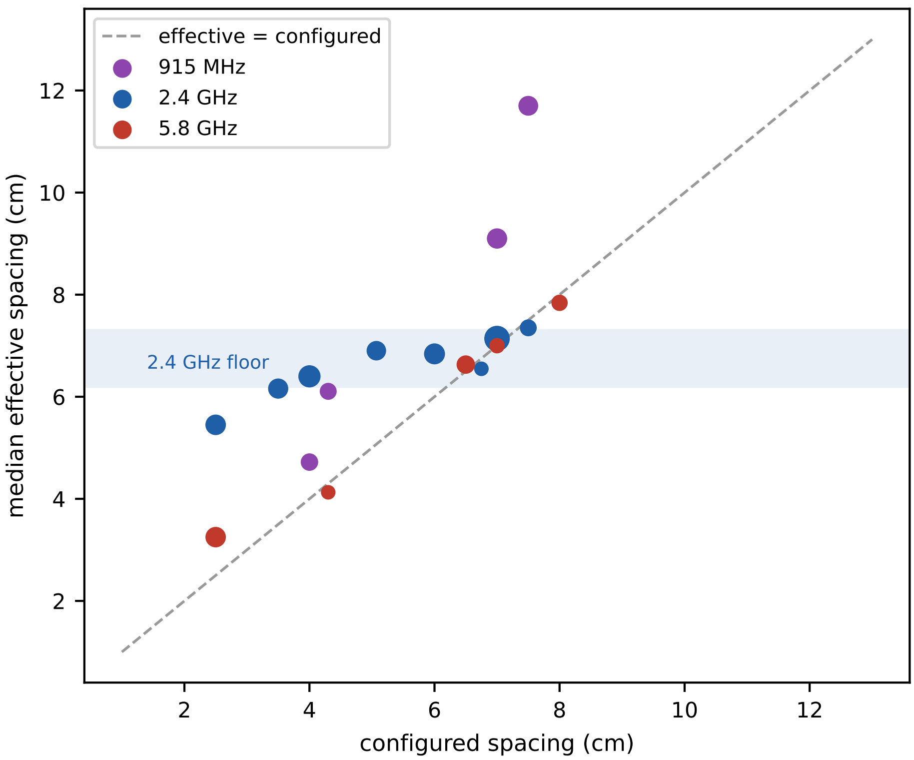


Fig. A2 — independent receivers
agree on g (corr 0.64)

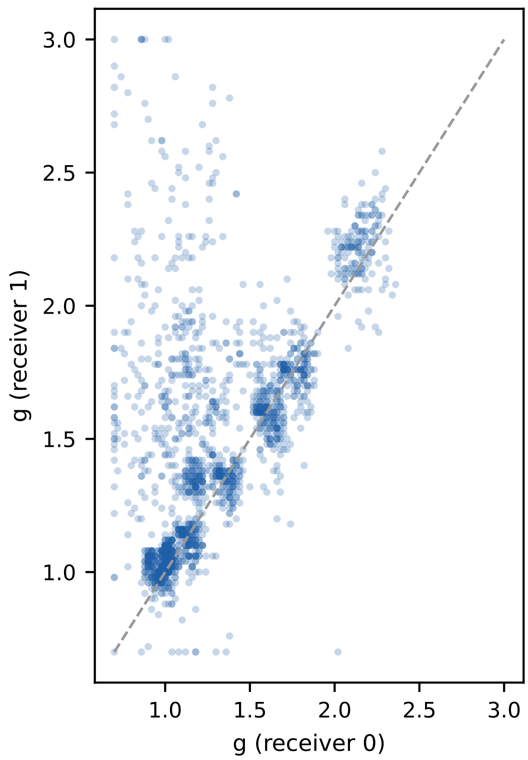

Fig. A3 — g distributions per config group: tight, group-specific, far from 1 for sub-floor configs

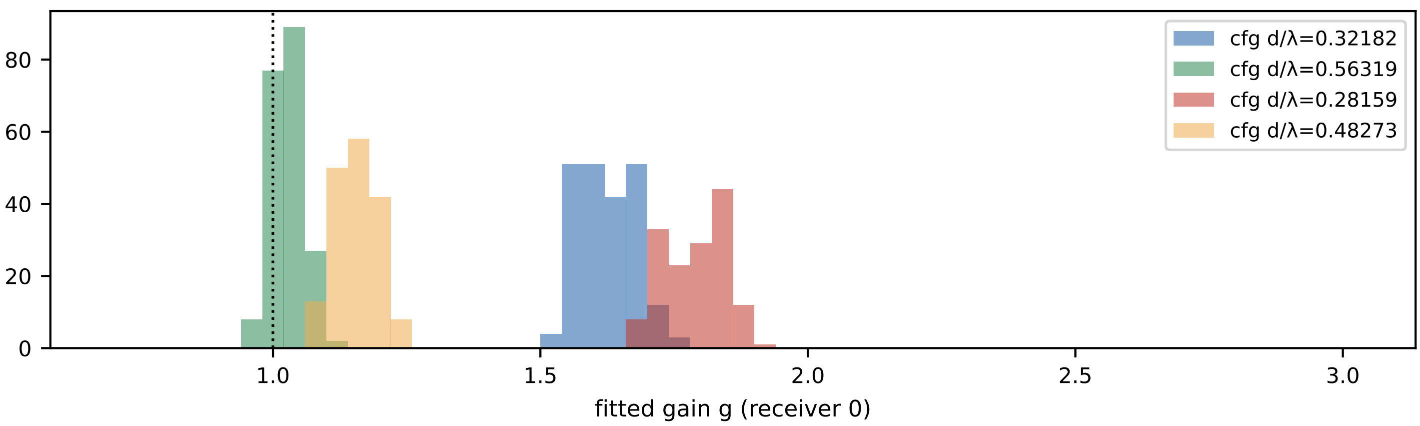
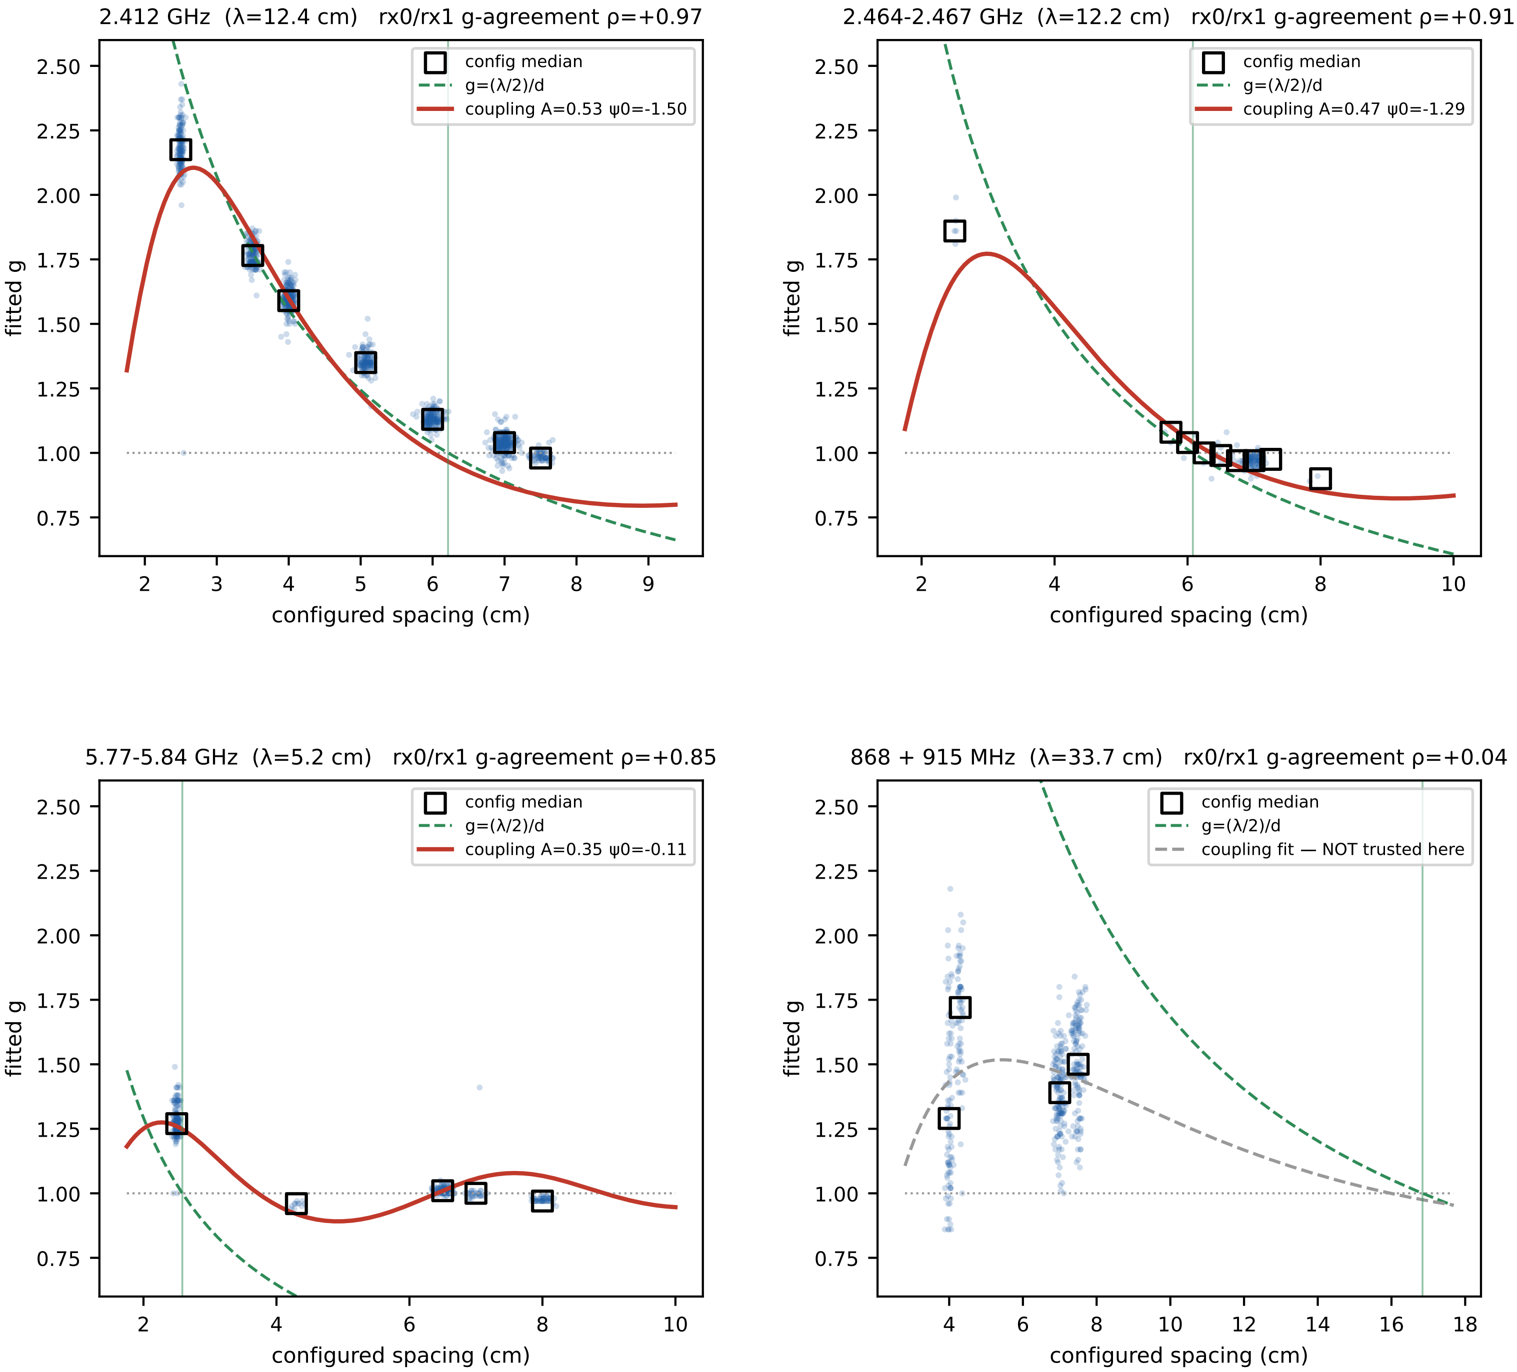


5b Per-band g vs configured spacing — coupling-model fits

Every wall dataset as a dot (mean of r0/r1 fitted g; bound-hitting fits excluded), per band. Overlaid: $g=1$ (config correct), the naive pin $g=(\lambda/2)/d$ (effective spacing stuck at half-wavelength), and a 2-parameter MUTUAL-COUPLING model. Model: each channel hears its own antenna plus a coupled copy of its neighbour, $V_0=1+Ce^{j\varphi}$, $V_1=e^{j\varphi}+C$, with $C(d)=A\cdot e^{j(\psi_0-kd)}/(kd)$ — the leading far-term of the classical mutual impedance between parallel elements ($C\approx Z_{21}/(Z_{11}+Z_L)$). Measured phase is $\arg(V_1V_0^*)$; its swing vs the ideal gives closed-form $g=(1-|C|^2)/(1+2\mathrm{Re}C+|C|^2)$. One (A, ψ_0) pair fitted per band on config medians, weighted by dataset count.



5b (cont.) Is the coupling fit reasonable?

FIT QUALITY (weighted rmse on config medians, 2 params/band; ρ = agreement of the two independent receivers on per-dataset g): 2.412 GHz: A=0.53, ψ0=-1.50, rmse=0.117, ρ=+0.97; 2.464-2.467 GHz: A=0.47, ψ0=-1.29, rmse=0.056, ρ=+0.91; 5.77-5.84 GHz: A=0.35, ψ0=-0.11, rmse=0.041, ρ=+0.85; 868 + 915 MHz: A=0.26, ψ0=-1.65, rmse=0.128, ρ=+0.04.

WHERE THE FIT IS NOT TRUSTWORTHY — 868/915 MHz. Per-dataset g is not a reproducible measurement in this band: the two independent receivers of the same rig agree at ρ=+0.97 (2.412 GHz), +0.91 (2.464), +0.85 (5.8) — but ρ≈ 0.0 at sub-GHz (median |g_r0−g_r1| = 0.58). Monte-Carlo shows plain Gaussian phase noise cannot do this (unbiased, sd≤0.1); the culprit is STRUCTURED SLOW DRIFT: sub-GHz residuals carry 2× the drift span (0.36 vs 0.19 rad) at junk-level corrected circstd (1.0), and simulated slow drift aliases into the fitted amplitude with sd≈0.47 when the geometric swing is only ±0.9-1.4 rad (d/λ=0.12-0.23) — matching the observed per-receiver scatter — while the same drift at d/λ=0.4 gives sd 0.28. Each receiver pair drifts independently, hence zero correlation. All sub-GHz data also comes from the Oct-2024–Jan-2025 degraded-hardware era (RX1 DC-offset / IF≈0 issues, weak signal). Config medians (n=51-156, SE≈0.05) still sit significantly above 1, so some expansion is probably real, but they may be drift-biased — the sub-GHz curve is drawn dashed-grey and excluded from any sidecar until re-measured in a healthy era.

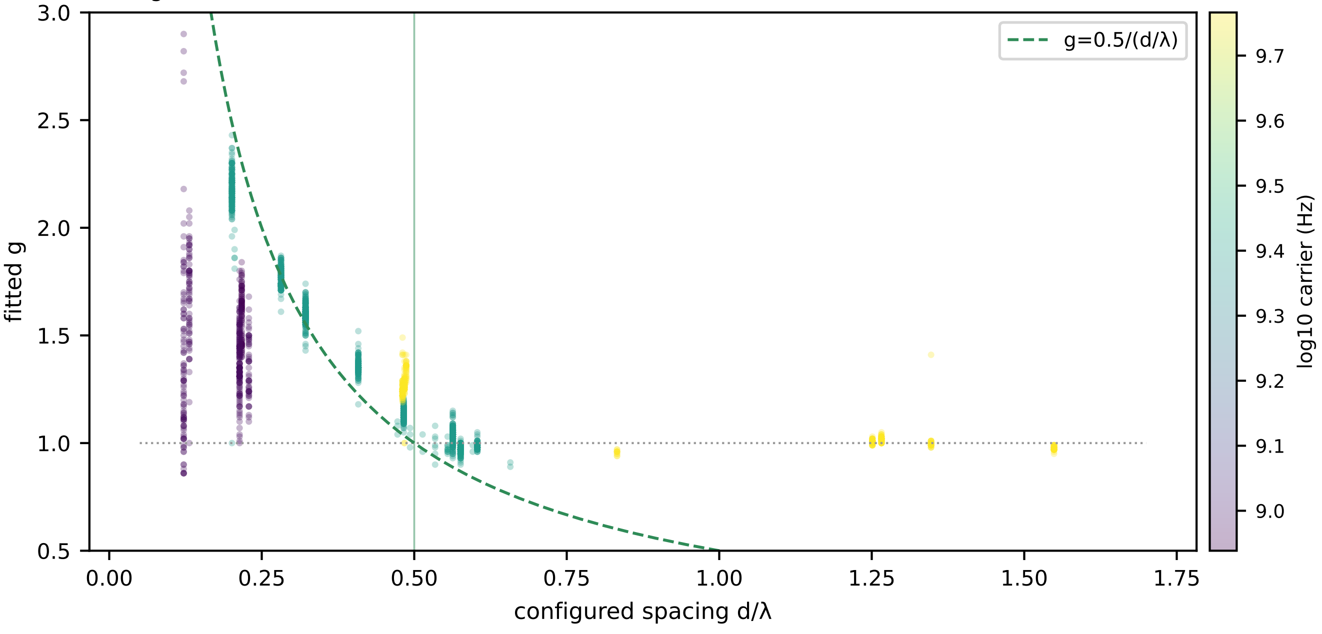
WHY IT IS REASONABLE. (1) The functional form is not an ad-hoc curve: C≈Z21/(Z11+ZL) with Z21 decaying as 1/(kd) and phase −kd is the leading far-term of the textbook mutual impedance between parallel elements. (2) Fitted coupling amplitudes are physical: A=0.2-0.5 keeps |C|<0.5 at every measured spacing — coupling weaker than the direct path, as it must be. (3) Cross-band consistency: A stays the same order of magnitude across a 6.4× frequency range, and the distortion is largest exactly where kd is smallest — the defining signature of coupling. (4) It predicts structure the naive λ/2-pin cannot: the ±8% oscillation of g around 1 at 2.4 GHz for 6-8 cm configs (Re C changes sign with kd); the moderate sub-λ/2 expansion at 868/915 MHz (g=1.2-1.6 where pinning would demand 2.3-4); and the near-λ/2 floors at 2.4/5.8 GHz. (5) g is a rig property (independent receivers agree, corr 0.64), and coupling is a rig-level EM mechanism — the right explanation class. (6) No overfitting: 2 parameters describe up to 9 config medians per band.

WHY TO STAY CAUTIOUS. (1) The model computes the broadside phase-swing slope; the scanner fits a full sine over the sweep — for the strongest coupling (2.5 cm at 2.4 GHz) these differ, so read A and ψ0 as effective, not literal. (2) A and ψ0 are lumped constants absorbing antenna type, load impedance, mounts and ground plane; each band uses different physical antennas, so per-band parameters cannot be checked against geometry without a bench measurement. (3) Identifiability is thin where configs are few: 5.8 GHz has effectively two informative spacings and 868 MHz only one, so ψ0 there is weakly constrained. (4) Competing mechanisms — phase-center displacement on the shared mount, near-field scattering off the plate — produce similar g(d) shapes at small kd; this fit cannot exclude them. (5) The 2.412 GHz rmse (0.12) is dominated by under-predicting the 6-8 cm wiggle: real Z21 has $1/(kd)^2$ and $1/(kd)^3$ near-field terms we dropped. (6) Observational data: config groups correlate with collection eras, though within-config stability across eras argues against a temporal artifact.

5b (cont.) Verdict and the universal view

VERDICT & USE. Treat the coupling fit as a physically-motivated 2-parameter summary and interpolator—good enough to generate an effective-spacing sidecar g(d, band) for correcting rx_spacing_input, and good enough to predict g for a NEW spacing config before collecting it. Do not treat it as validated first-principles EM: the decisive test is a bench VNA S21-vs-distance sweep on the actual mounts (one afternoon), or a controlled spacing sweep at fixed era. If either matches the fitted C(d), the sidecar can be trusted fleet-wide, including for spacings never collected.

Fig. B4 — all wall datasets, universal axis: distortion is a function of d/λ, onset below ≈0.5



6 Deep dive — NaN / no-signal snapshots

WHAT NaN MEANS. mean_phase is computed only over windows classified as signal (coherent phase, stddev<0.5, or amplitude>40). If a snapshot has NO signal windows, mean_phase = NaN — silence is represented explicitly, never averaged in. NaN is therefore a DUTY-CYCLE descriptor, not by itself a defect: the wall blaster transmits continuously (baseline ≈0% NaN) while the rover's WiFi/o4 emitter is bursty (healthy baseline 60-70% NaN).

THE DISCRIMINATOR (fig. N2): plotting NaN% against the quality of the VALID part separates two populations. Rover: high NaN with clean valid part — intermittent but healthy. Wall bad-months: elevated NaN AND noisy valid part — a degraded capture, not a bursty emitter. A NaN gate alone cannot make this distinction; the pair (NaN%, valid-part circstd) can.

GATES (v2, applied in this scan): wall two-tier — 5-20% = FLAG (142 datasets, kept usable), >20% = QUARANTINE; rover unchanged (>90% or <100 valid snapshots = no_signal). Root-causing low-SNR vs absent-emitter needs the planned burst-SNR metric (section 13): signal-window amplitude vs noise-window amplitude.

Fig. N1 — NaN% by platform, with gates
(wall 5/20% two-tier; rover 90%)

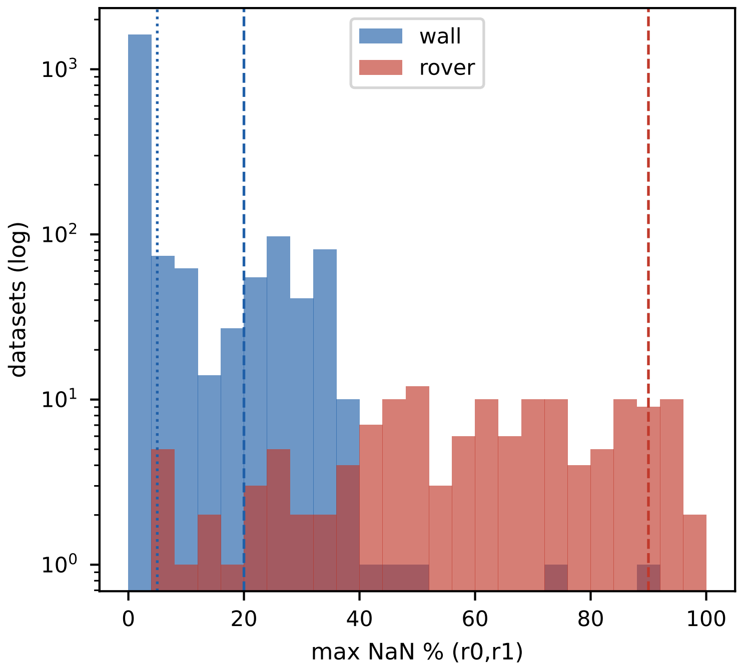


Fig. N2 — the discriminator: duty cycle vs
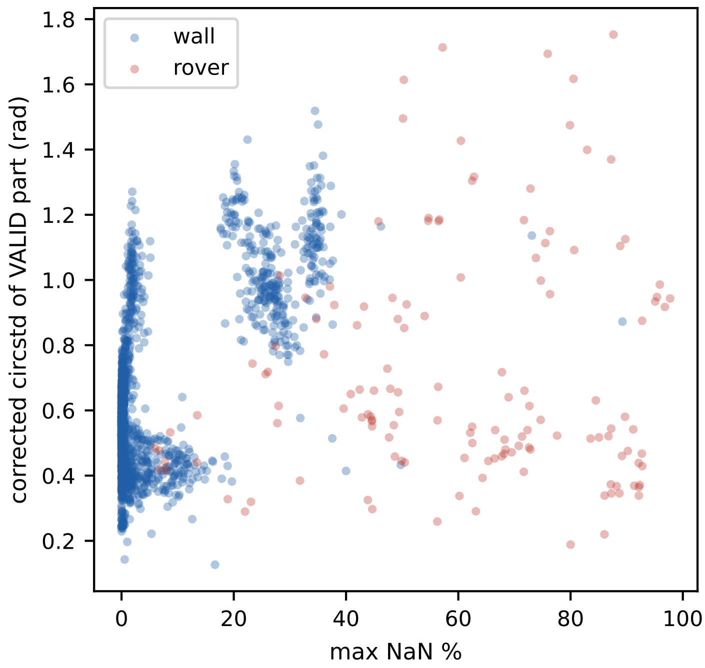
capture quality are separable



Reading fig. N2: the rover cloud sits at high NaN / moderate circstd (its GPS floor) — bursty but fine. The wall cloud splits: the dense mass at (0%, 0.4-0.6) is healthy; the arm extending right AND up is the Oct/Nov-24 + Feb-25 era (section 7) — NaN and valid-part noise rise TOGETHER, the signature of a weak/degraded signal chain rather than an intermittent emitter.

6b Deep dive — IF placement: the tone-at-DC failure mode

WHAT IF MEANS HERE. The receiver mixes the antenna signal with its local oscillator (LO); the beacon then appears in the complex baseband at the INTERMEDIATE FREQUENCY IF = f_carrier - f_LO. IF is where the tone sits relative to 0 Hz (DC) in the captured IQ. DC is the worst place in the spectrum to park a signal: it hosts the ADC/mixer DC offset, LO leakage, 1/f noise — and, critically, the AD9361's RF-DC and baseband-DC (BBDC) tracking loops, whose job is to NULL whatever sits at DC. A beacon within the loop bandwidth gets slowly attenuated and phase-rotated, independently in each receiver — which is exactly the slow drift that destroyed the sub-GHz gain fits (section 5b): rho(r0,r1)~0, per-dataset g scatter 0.2-0.5.

WHY SUB-GHZ LANDED ON DC — the IF existed but was UNDER-MARGINED. All configs set f-intermediate = 100 kHz (verified in recorded config blobs). But crystal wander scales with carrier (ppm × f_c; Pluto XO correction is an uncalibrated 40.000000 MHz), and at 915 MHz it is 50-140 kHz — the size of the offset itself: nominal +100 kHz measured as +48 kHz (r0) and -39 kHz (r1) — through DC. At 2.412 GHz ~10% of board/emitter combos cancelled to ~0 (that band's noisy tail); at 5.8 GHz the 2.4×-larger wander threw the tone far from DC and saved the band. Lesson: f_IF must dominate wander (≥10×), i.e. scale with carrier. [Measurement: FFT peak of one raw snapshot per dataset, n=160, 40/band; data_quality_reports/if_analysis/sample_if.py]

Fig. C1 — phase quality vs measured tone offset from DC

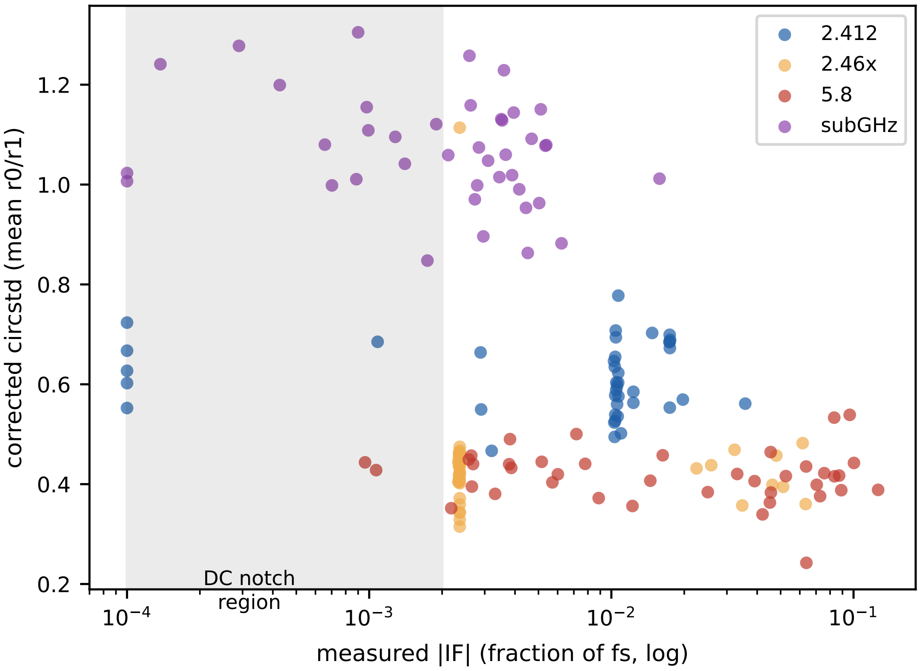


Fig. C2 — the cliff is the DC notch, not IF magnitude

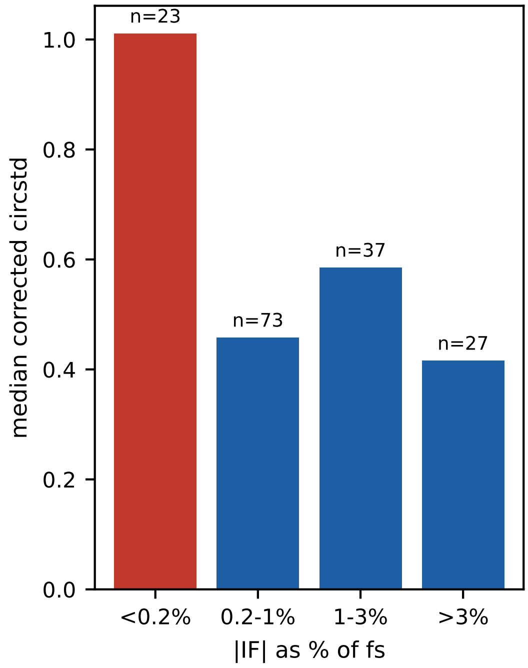

Fig. C3 — where each band's tone actually sits: sub-GHz (and part of 2.412) in/around the notch

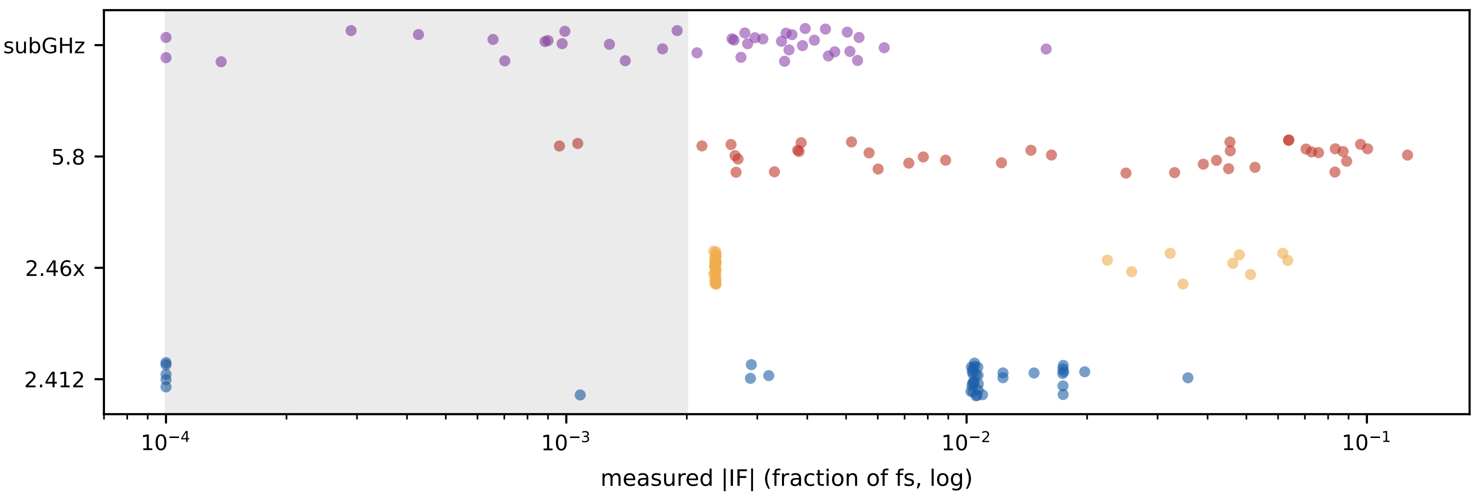

6b (cont.) IF vs captured signal — recommendations

PER-BAND SUMMARY (sampled): 2.412: |IF|med=0.0105·fs, p10=0.0001, DC-power=0.04, tone-purity=0.15, circstd=0.60 (n=40) | 2.46x: |IF|med=0.0024·fs, p10=0.0023, DC-power=0.00, tone-purity=1.00, circstd=0.43 (n=40) | 5.8: |IF|med=0.0207·fs, p10=0.0026, DC-power=0.02, tone-purity=0.12, circstd=0.42 (n=40) | subGHz: |IF|med=0.0028·fs, p10=0.0004, DC-power=0.04, tone-purity=1.00, circstd=1.07 (n=40).

READING IT. (1) 2.46x sits at |IF|~0.0024·fs (~38 kHz) — barely past the notch — and is HEALTHY (circstd 0.43, pure tone): the boundary is sharp and sits near 0.002·fs (~30 kHz at 16 MS/s), i.e. the BBDC loop / DC-offset region, not a gradual SNR effect. (2) Within 5.8 GHz, quality is FLAT vs IF (0.41-0.44) once past the notch — IF placement beyond the notch does not matter in the sampled range (<0.1·fs). (3) IMPORTANT LIMIT OF THE CLAIM: sub-GHz samples where BOTH receivers clear the notch still show circstd~1.0 — the DC collision cleanly explains the g-fit irreproducibility (independent per-receiver drift aliasing, section 5b) but NOT the band's whole quality problem; the degraded Oct-24-Jan-25 era and the wider near-DC 1/f skirt also contribute, and a single-snapshot IF measurement misses tone wander through the notch. (3b) Sub-GHz sits inside the notch (median 0.0028, quartile 0.0004) with up to 100% of window power in the DC region — circstd median 1.07 = uninformative. (4) Tone purity separates emitters: sub-GHz/2.46x are pure CW (tone-purity=1.0); 2.412 (live Wi-Fi channel) and 5.8 (wideband analog video) spread power (0.12-0.15) — for those, per-subcarrier or wider-band processing is the eventual win, but DC avoidance still applies.

RECOMMENDATIONS — IF POLICY FOR FUTURE CAPTURES. (R1) The historical f_IF = 100 kHz is under-margined, not absent. Set f_IF ≥ 10× worst-case crystal wander (measured wander: 50-140 kHz at 915 MHz, up to ~600 kHz at 5.8 GHz) AND ≥ 0.01·fs — i.e. f_IF must scale with the carrier. (R1b) Calibrate each Pluto's xo_correction (currently a factory-default 40.000000 MHz on the probed units) — a one-time per-board trim shrinks the wander itself by an order of magnitude. (R2) Keep f_IF ≤ min(rf_bandwidth, fs)/2 − guard so the tone stays inside the analog passband; a good universal choice here is f_IF = fs/16 (1-2 MHz), echoing the lab-log observation that larger IF 'seems to help' and 'maybe proportional'. (R3) Run a small controlled sub-GHz A/B first: a few sessions with f_IF per R1 vs LO=carrier, same rig, same week. If quality recovers to 2.46x levels (both are pure CW), commission the full re-capture; if not, the residual sub-GHz problem is era/hardware and needs the bench. (R4) If a small IF is ever unavoidable, disable BBDC tracking for that session (bb_dc_offset_tracking_en=0) and accept a static DC spur instead of a moving notch. (R5) Scanner v3: record measured IF per dataset (one FFT per capture, ~free) and gate |IF| < 0.002·fs as QUAR:tone_at_dc — it is a stronger, physical predictor of the drift/quality failure than any downstream statistic. (R6) Firmware/config hygiene: log the configured f_IF alongside rx_lo in the capture yaml so nominal-vs-measured IF drift becomes auditable.

6b (cont.) IF policy — off-center is free

Q1 — CAN A BETTER IF MAKE THE WHOLE DC/BBDC QUESTION MOOT? Yes. With f_IF = fs/16 the tone sits ~30× outside the DC-tracking loop bandwidth, so every loop (BBDC, RF-DC, quadrature) can stay ON at its default: the loops then only keep the DC region clean and never touch the signal. No new config knob, no headroom cost, no bits lost. Production policy adopted: f_IF = fs/16, all tracking on; the 2×2 BBDC matrix (E-IF1) is demoted from policy question to diagnostic (docs/future_experiments.md).

Q2 — SHOULD IF BE 0-CENTERED OR OFF-CENTER? Never 0-centered. DC hosts everything bad in a direct-conversion receiver at once: the tracking notch, ADC/mixer offsets, LO-leakage spur, the 1/f noise skirt — and the quadrature image (IQ imbalance mirrors the tone to −IF, which at IF=0 lands exactly ON the tone). Off-center is COMPLETELY FREE for the measurement: both RX channels share one LO, so the IF rotation e^{j2π·f_IF·t} is identical in both channels and cancels exactly in x1·x0* — the measured phase difference is the same at any IF. Amplitude statistics and segmentation are equally indifferent. The only window constraint: |IF| ≥ max(10× crystal wander, ~0.01·fs) at the bottom, ≤ passband/2 − signal bandwidth at the top (wideband signals like 20 MHz Wi-Fi at 30 MS/s need care; CW beacons do not).

Q3 — IF BBDC TRACKING WERE DISABLED, WOULD IT ADD NOISE? No. The BB DC offset is a quasi-static complex CONSTANT, not noise; the loop removes an offset, and disabling it simply leaves that offset in the data as a static DC spur. The noise floor away from DC (thermal, 1/f, quantization) is identical either way. With proper IF the spur is spectrally separated and its bias on the window phase product is ~(offset/signal)²: for the near-rails 915 beacon and a −30 dBFS spur, ≈0.3% ≈ 0.003 rad — two orders below the noise floor. And a static spur is RECORDED — trivially removable from raw IQ in post — whereas the loop's time-varying correction is unlogged and irrecoverable, which is exactly what made historical sub-GHz data unrescuable.

Q4 — AMPLITUDE BITS AND SPUR MAGNITUDE. Direct headroom cost of an offset |c| on the 12-bit ADC (±2048) is log2(2048/(2048−|c|)): 0.07 bits at 5% FS, 0.3 bits at 20% FS — negligible until the spur is a large fraction of full scale. The sneaky path is the AGC: it regulates TOTAL power including the spur, so a large spur makes it back off gain and shrink the signal's share of the range. And the spur is GAIN-DEPENDENT (LO self-mixing is amplified with the signal): largest at high AGC gain = weakest signal — precisely the rover regime, where the near-rails 0.3% estimate does NOT transfer. That offset-vs-gain curve is unknown for our boards; E-IF1's manual-gain sweep measures it. Conclusion: with the fs/16 policy none of this is exercised — tracking stays on and the spur question never arises in production.

7 Deep dive — the bad-capture months

THE FINDING. 431 wall datasets exceed 5% NaN mean_phase (289 quarantined at >20%, 142 flagged at 5-20% under the v2 two-tier gate; what NaN means: section 6). They are NOT randomly spread: they cluster hard by collection month — Nov 2024: 100% of the month's datasets, Oct 2024: ~47%, Feb 2025: ~35%, against 0/855 for Jun-Sep 2024. Crucially the VALID part of these datasets is also degraded (median corrected circular stddev ≈0.96 rad vs fleet ≈0.57, fig. B2) — a capture-quality era, not merely a bursty emitter.

INTERPRETATION: a genuine capture-quality era — something about the rig, emitter, or RF environment degraded in Oct-Nov 2024 (partially recovered Dec, relapsed Feb 2025). This is not a segmentation-threshold artifact and not related to the spacing mislabeling. RECOMMENDATION: quarantine stands for the >20% NaN group; the 142 datasets at 5-20% NaN are borderline — decide after checking whether their valid-part circstd is clean; investigate what changed at the rig in those months (emitter power? antenna cable? gain settings?).

Fig. B1 — phase quality by month (ALL wall): the bad months are noisy, not just NaN-heavy

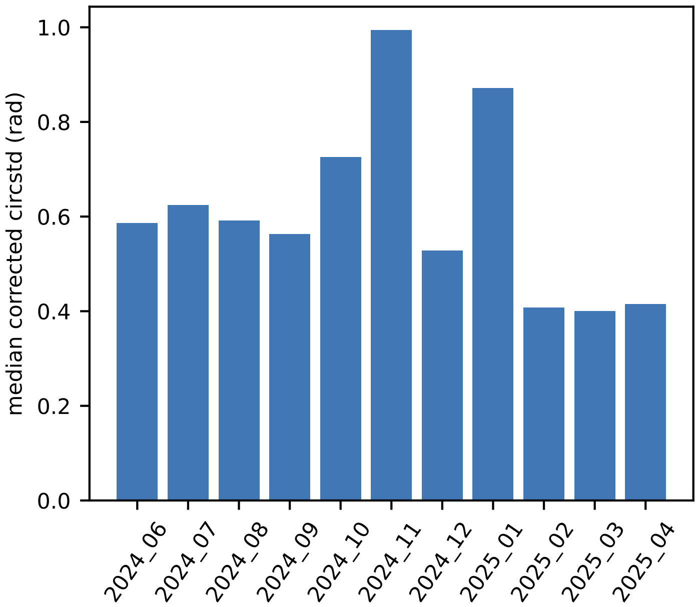

Fig. B2 — even their VALID snapshots are noisier: a capture-era problem

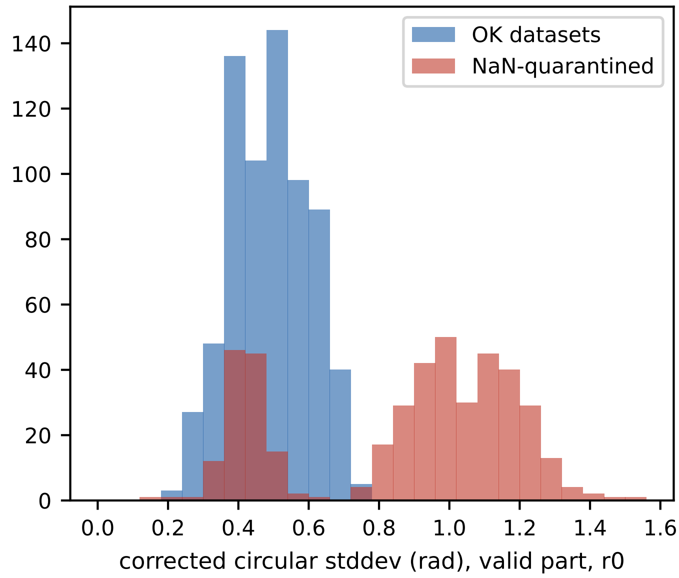

Fig. B3 — NaN-quarantine rate by month: Nov 2024 = 100%, Jun-Sep 2024 = 0%

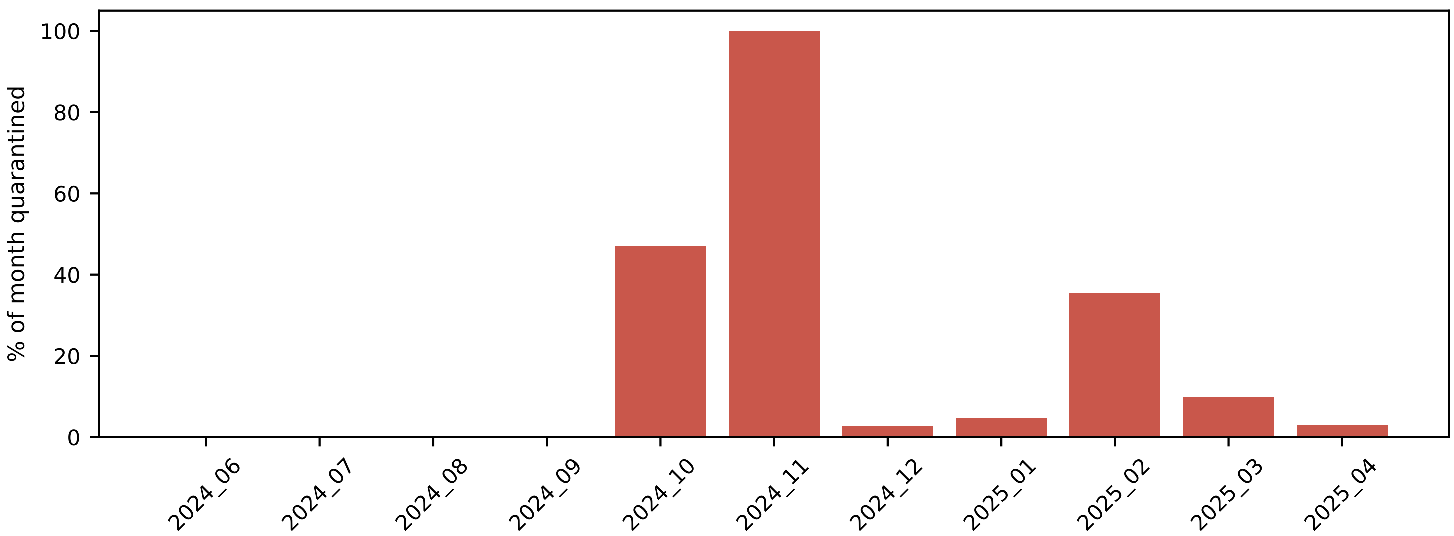


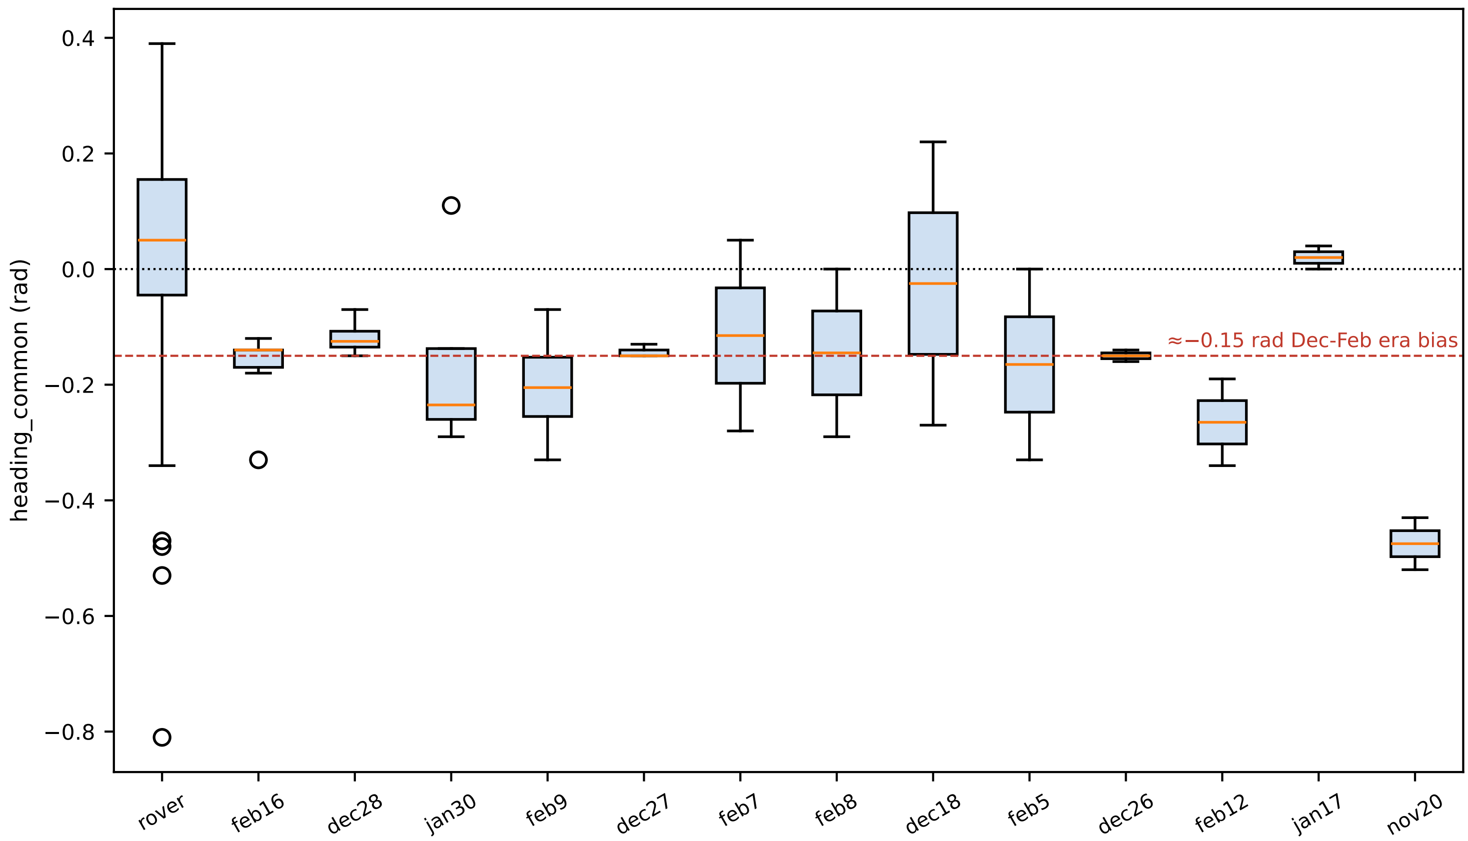
8 Deep dive — rover heading bias & mount anomalies

THE FINDING. The common component of the two receivers' fitted Δθ isolates a HEADING bias (both arrays shift together only if the craft heading is wrong). Dec-Feb missions consistently show −0.14..−0.33 rad; the later 'rover*'-era missions center near +0.04 (fig. C1). The bias is therefore era/installation-dependent and stable within an era — an ideal 1-parameter correction, fitted per day or era.

SCANNER CAVEAT + ANOMALIES: 73/139 rover fits hit the Δθ grid bound (±0.35) — a v1 scanner limitation. Wide re-fits (±0.9) split these into (a) larger-but-plausible heading biases (common −0.28..−0.34) and (b) a few sessions with large DIFFERENTIAL mount anomalies — feb7_mission1_rover1 r1 = −0.72 rad (≈41°), feb8_mission1_rover1 r1 = +0.54 rad — i.e. one array rotated/miswired relative to config. Those specific sessions are genuinely suspect and should be excluded or inspected individually.

Also note the rover noise floor: at 9-13 m range, 2-5 m GPS error alone predicts 0.15-0.5 rad of bearing noise — the observed post-correction circstd (~0.45-0.6) is consistent with GPS-dominated labels, so rover metrics compare the residual against this predicted floor rather than against zero.

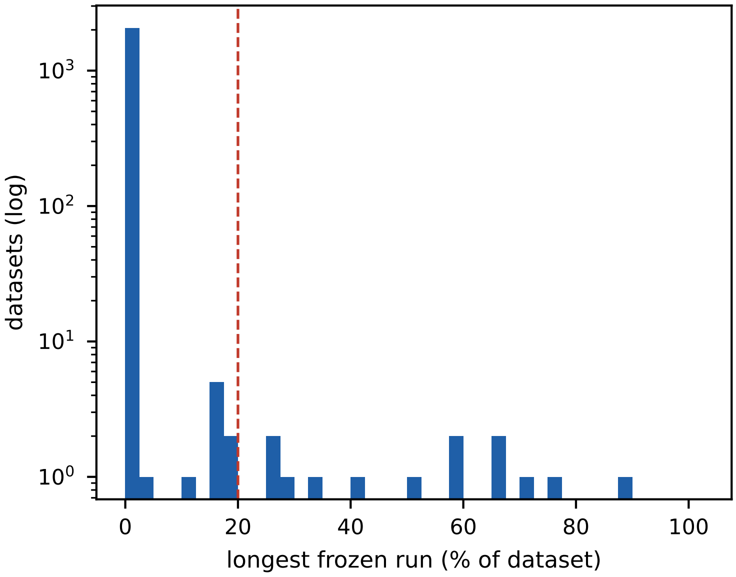
Fig. C1 — common-mode Δθ (heading bias) by mission day/era: stable within era, differs across eras



9 Deep dive — stale positions (#42 in the wild)

THE FINDING. KNOWN_ISSUES #42: if the GRBL planner thread dies (e.g. an out-of-bounds point), data collection keeps recording while the position cache freezes — every subsequent snapshot is stamped with the same stale position, silently corrupting labels. The scanner detects the signature (a long frozen run that reaches the end of the dataset): 21 wall datasets carry it. These should be excluded, or truncated at the freeze point (the data before the freeze is fine).

Fig. D1 — frozen-run length across the wall fleet
(the 21 tail-frozen sit in the right tail)



The 21 frozen-tail datasets:

```
wallarrayv3_2024_06_18_12_41_08_nRX2_rx_  (16%)

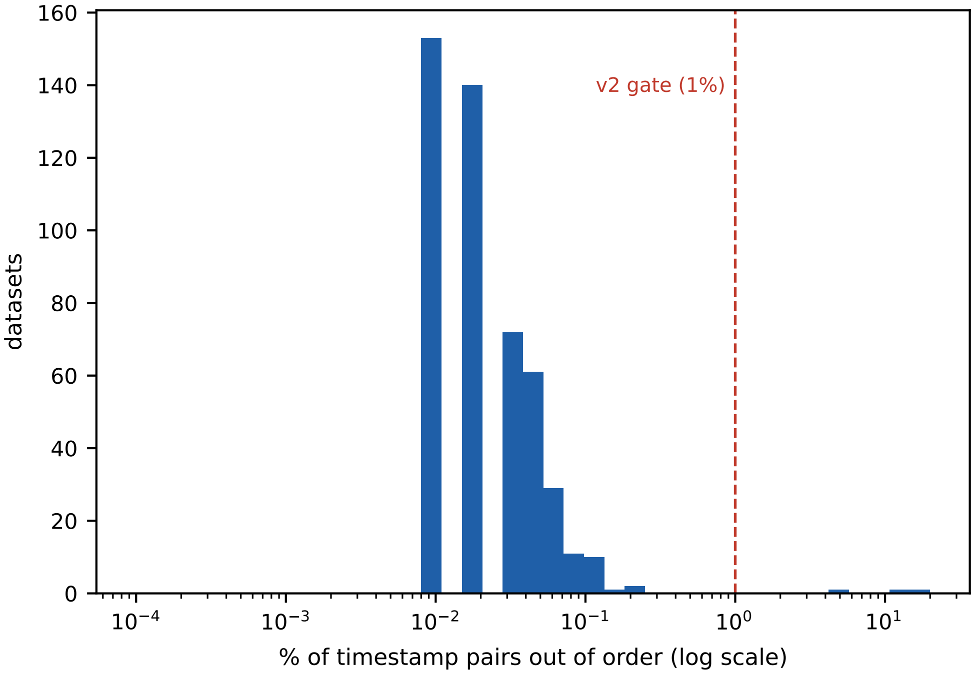
wallarrayv3_2025_01_13_15_25_02_nRX2_bou  (16%)
wallarrayv3_2025_01_22_05_11_03_nRX2_bou  (26%)
wallarrayv3_2025_01_22_13_07_56_nRX2_bou  (89%)
wallarrayv3_2025_02_04_22_09_18_nRX2_bou  (29%)
wallarrayv3_2025_02_05_14_41_04_nRX2_bou  (42%)
wallarrayv3_2025_02_11_04_34_20_nRX2_bou  (17%)
wallarrayv3_2025_02_23_07_34_53_nRX2_bou  (11%)
wallarrayv3_2025_02_24_08_52_47_nRX2_bou  (18%)
wallarrayv3_2025_02_23_19_18_48_nRX2_rx_  (35%)
wallarrayv3_2025_02_28_21_32_16_nRX2_bou  (75%)
wallarrayv3_2025_03_04_01_34_14_nRX2_bou  (66%)
wallarrayv3_2025_03_08_15_54_21_nRX2_bou  (16%)
wallarrayv3_2025_03_15_14_42_41_nRX2_bou  (16%)
wallarrayv3_2025_04_16_21_16_43_nRX2_bou  (19%)
```

Note the histogram's mass near zero: normal bounce/circle motion updates positions every snapshot, so any frozen run beyond a few percent is anomalous. The red line marks the detector threshold; only runs that ALSO reach the final snapshot are classified as #42 tails (mid-run pauses exist, e.g. planner restarts).

10 Deep dive — timestamp monotonicity

THE FINDING. 482 datasets contain at least one non-monotonic timestamp pair, but the distribution (fig. E1) shows the median affected fraction is ~0.02% of pairs (a handful of samples out of hundreds of thousands): benign clock jitter, likely NTP adjustments during collection. The v2 gate (applied in this scan) flags only the 3 datasets above 1% — those have real timestamp problems worth individual review (cadence anomalies can corrupt time-interpolated ground truth).

Fig. E1 — timestamp violations: overwhelmingly trivial jitter



Datasets above the 1% gate: 3. Everything below it is reported as info and no longer affects the quality bin.

11 Deep dive — correction payoff (raw vs corrected)

For every dataset the scanner fits the ≤3-parameter systematic model and reports the residual circular stddev before and after. Fleet-wide medians (v2 grids): wall 0.878 → 0.572 rad, rover 0.844 → 0.580 rad. Fig. F1 shows the per-dataset improvement; points far below the diagonal are datasets whose apparent noise was mostly a correctable systematic (the gain groups); points on the diagonal are already-clean or genuinely noisy (the bad months).

Fig. F1a — wall (n=2088)

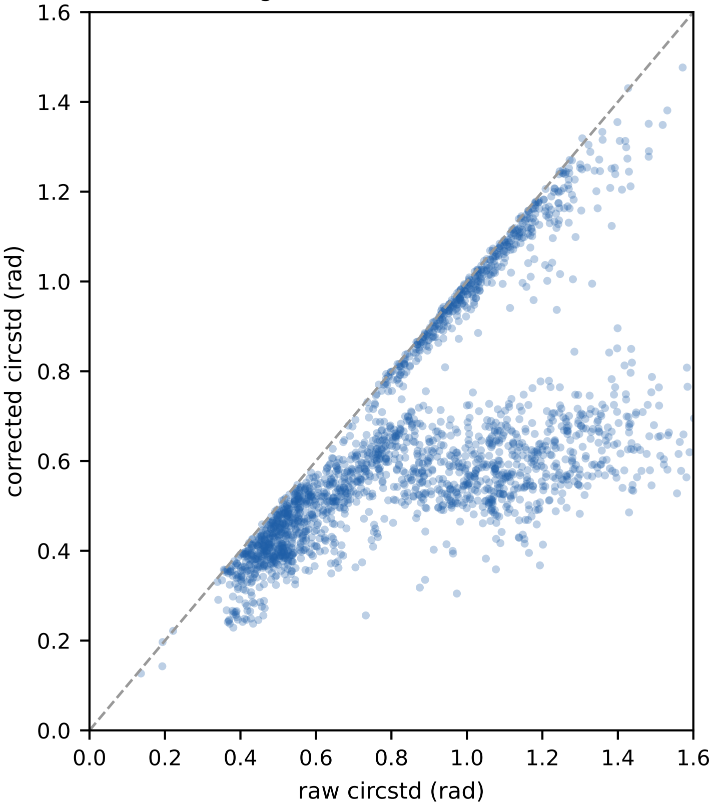


Fig. F1b — rover (n=139)

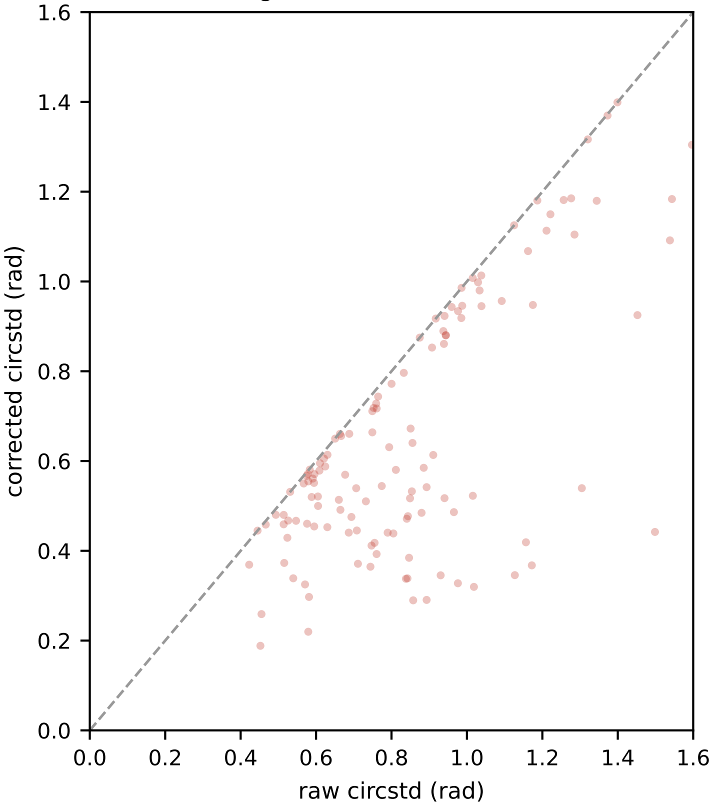

Reading: the wall cloud shows a dense band pulled well below the diagonal (the gain systematic absorbing 30-50% of apparent noise) plus a diagonal population near (1.0, 1.0) — the bad-month era whose noise is NOT explained by any low-dimensional systematic. The rover cloud improves more modestly (heading bias removal), sitting on its GPS-induced floor of ~0.45-0.6 rad.

12 Deep dive — scan errors (integrity failures)

23 datasets could not be scanned at all. Every error is itself a data integrity finding, in four groups:

9× yaml-vs-zarr mount-angle mismatch

AssertionError comparing rx_theta_in_pis in the yaml config against the recorded zarr value— the dataset's mount metadata contradicts itself.

6× unreadable/corrupt zarr

the store fails to open — truncated or damaged LMDB.

6× missing segmentation cache

no v3.7 .yarr/.pkl in the precompute cache — never segmented.

2× rx_spacing not constant within dataset

the per-snapshot spacing field changes mid-dataset (thousands of mismatches)— collection-time config drift.

Full list:

13 Scanner improvements — v2/v3 roadmap

The v1 scanner did its job (it found the systematics and the bad eras) but this scan also measured the scanner itself. Planned changes, with the evidence that motivates each:

v2 — gates and fits (IMPLEMENTED — this report uses the v2 scan)

1. Widen wall gain grid to [0.7, 3.0] — the cfg-0.20λ group pinned at the 2.0 bound (true g ≈ 2.0-2.5).
2. Widen rover Δθ grid to ±0.9 rad — 73/139 rover fits hit the ±0.35 bound; real biases reach −0.72.
3. Two-tier wall NaN gate: 5-20% = FLAG, >20% = QUARANTINE (142 borderline datasets were over-quarantined).
4. Timestamp gate at >1% of pairs (median violation is 0.02% — benign NTP jitter; only ~3 datasets exceed 1%).
5. Common/differential Δθ decomposition for the wall too (separates shared geometry error from per-array mount).
6. Coverage-aware fitting: skip multi-parameter fits when angular coverage is narrow (g and Δθ degenerate).
7. Serial re-check of ERROR datasets (12-way parallel LMDB opens can fake 'unreadable' via lock contention).
8. Frozen-tail: emit the truncation index so #42 datasets can be salvaged (prefix is good data) instead of dropped.

v3 — new metrics and detectors (planned)

9. Duty-cycle descriptor: signal-window fraction + its time profile (a characteristic, never a failure).
10. Burst SNR: median |signal| in signal-windows ÷ noise-windows — free per-dataset SNR; would root-cause the bad months (weak emitter vs receiver degradation) directly from cached data.
11. Noise-floor tracking from the noise windows — a free receiver-floor calibration per dataset; drift across eras flags gain/AGC changes.
12. SNR-weighted residual fits: weight each snapshot by window count × inverse phase-stddev.
13. Time-lag Δt fit (plan M10): rover tx/rx clock alignment via residual concentration over lag.
14. Interference detectors (for coherent in-band transmitters, which defeat the coherence test): (a) two-component von Mises + uniform mixture on the residual → interferer fraction + its angle; (b) static-source back-projection — contaminated snapshots cluster at one WORLD angle while GT moves, localizing the interferer; (c) cross-receiver coherent-outlier test (both receivers wrong consistently = interferer, independently = noise); (d) second-peak persistence in the cached windowed beamformer.
15. Calibration sidecar emission: per-(dataset × receiver) fitted (c, g, Δθ) with the plan's guards — time-split stability, rig-consistency, bounded priors, minimum-improvement threshold.
16. Per-config-family gain gate: flag |g − median_g(config)| > 0.15 instead of |g−1| > 0.25 — silences the known coupling floor (§5b), catches true per-capture anomalies (the 43↔47 mm class).
17. tone_at_dc gate: measure IF per dataset (one FFT of one snapshot, ~free) and QUARANTINE |IF| < 0.002·fs (§6b) — a physical, upstream predictor of the drift failure.
18. Beamformer-based metrics from the cached weighted_beamformer: offset-corrected GT-bin percentile (alignment) + entropy (informativeness) — scores datasets on the representation the NN consumes; works where scalar g fits fail (sub-GHz). Offset must be fitted first or it confounds informativeness.

Evidence for the interference detectors is already in this scan: the 2025-04-05 rover session (7 datasets, structure 0.98-1.45, 55-65% outliers) is a discrete interference/multipath incident, and the 915 MHz band shows 2.3× the structured residual of the other bands fleet-wide. Full experiment queue with designs and decision rules: docs/future_experiments.md.

14 Recommended actions

1. Physical rig check (10 minutes, highest leverage)

Measure the actual minimum achievable antenna spacing on the 2.4 GHz wall arrays. If ~6.5 cm, the sub-floor configs are confirmed mislabeled; if smaller, mutual coupling is the cause. Either way the fitted effective d/λ is the number the pipeline should use.

2. Clean split files

Exclude from the next training split: the >20% NaN bad-month datasets, the 21 frozen-tail datasets (or truncate at freeze), the 23 error datasets, and the rover mount-anomaly sessions (feb7/feb8 mission1). Roughly 480-500 datasets, all era-clustered.

3. Calibration sidecar

Emit per-(dataset × receiver) fitted (c, g, Δθ) with the plan's guards (time-split stability, rig consistency, bounded priors, minimum improvement). Feed empirical tables and filters first; A/B a retrain with corrected spacing/labels after.

4. Scanner v3 (v2 shipped — this report)

Per-config-family g gate, tone_at_dc quarantine, beamformer alignment/entropy metrics (roadmap items 16-18); all computable from existing caches, no new capture needed.

5. Collection-time gates

Run Tier-1 metrics inside data_collector at capture time so a Nov-2024-style bad era or a frozen planner is caught in the field within minutes, not months later.

6. IF policy + the 2×2 capture matrix (one afternoon)

Adopt §6b R1/R2 (explicit f_IF, fs/16 default; never LO = carrier). Run E-IF1: {IF=0, IF=fs/16} × {BBDC tracking on, off} at 915 MHz on the wall rig — decides whether IF placement alone rescues sub-GHz or the BBDC knob is also needed. Prereq: a one-line bb-dc-tracking receiver key in PPlus.setup_rx_config. Design: docs/future_experiments.md.

7. Training-data ladder (RUNNING)

Stage-1 base/r1/r2 × 250k steps launched 2026-07-12 with val_subset_groups (val_clean/degraded/band915); successive halving on val_clean/single_loss. Baselines from the jun26 checkpoint: 0.09735 / 0.1014 / 0.10902 / 0.11003.

Appendix — per-file quality and issues (all datasets)

Sorted by platform then name. stat: OK / FLAG (usable, has a known systematic) / QUAR (fails validity gate) / ERR. nan% = max(r0,r1) invalid-phase fraction. raw>cor = r0 circular stddev before/after the fitted correction (rad). g0/g1 = fitted gain per receiver (effective/configured spacing). dth0 = fitted mount shift (rad). Issues = gate reasons.
